T Systems

Automated penetration testing under a minute

What is penetration testing in security?

It's a simulated cyber attack against your computer system to find exploitable security weaknesses.

Why?

It helps organizations to assess their security posture, prioritize remediation efforts, and save costs on real-world attack prevention.

What is automated penetration testing?

It's a type of penetration testing that uses automated software tools to simulate cyber attacks on a network or system, helping you find vulnerabilities faster and more consistently.

Automated pentesting in action

1 Target discovery

(Asset discovery, network mapping)

Identifies and maps out all the devices, systems, and networks in your IT environment to create a complete inventory.

2 Fingerprinting and reconnaissance

(Vulnerability scanning, service enumeration)

Collects system and application information to identify potential vulnerabilities and entry points.

3 Vulnerability scanning

(Vulnerability mapping, service enumeration)

Scans for known flaws such as outdated software, misconfigurations, or weak passwords.

4 Exploitation

(Attack simulation, vulnerability exploitation)

Attempts to exploit found vulnerabilities to gain unauthorized access.

5 Privilege escalation

(Root access attempts, lateral exploits)

Tries to gain higher-level permissions, such as admin or root privileges, after an initial breach.

6 Lateral movement

(Pivoting, network propagation)

Moves from one system to another to explore deeper into the network.

7 Persistence simulation

(Backdoor creation, access retention)

Tests whether attackers can maintain long-term access to the compromised system.

8 Risk prioritization

(Threat scoring, risk ranking)

Ranks vulnerabilities based on how dangerous they are, helping you focus on the most critical issues first.

9 Reporting and evidence

(Proof of concept, audit trail creation)

Provides a list of attack vectors and methods, with evidence, for remediation or compliance needs.

10 Retesting

(Validation, post-remediation checks)

Runs tests against specific vulnerabilities to confirm they've been successfully resolved.

AI + Automation packs a punch in pentesting

Autonomous testing
Runs constantly, finds vulnerabilities and runs test results automatically.

Smart decisions
Learns from each test to find more and adapt to how you think.

Zero touch
Needs no human input for execution or retesting.

Clear reporting
Delivers easy-to-understand reports and action items.

You should also know

48% of apps contain critical risks[1]

5 million shortfall in cyber security personnel[2]

180% increase in exploitation of vulnerabilities in 2024[3]

Average cost of data breach in 2025 **$4.8 million**[4]

The window to act on vulnerabilities is shrinking from **74 days (2014)** to just **5 days (2025)**[5]

Business benefits

- Speed and scale
- Cost-efficiency and savings
- Real-world simulation
- Continuous security
- Better risk management?
- Audit-ready reports
- Compliance
- Visibility
